## Decoding the Enigma: A Deep Dive into LC135 v1

LeetCode problem 135, version 1 (LC135 v1), presents a captivating puzzle in dynamic computational thinking. This intriguing problem, concerning allocating candies to children based on their relative ratings, demands a nuanced understanding of greedy approaches and refinement strategies. This article will unravel the intricacies of LC135 v1, providing a comprehensive guide to its solution, along with practical implications and observations.

The problem statement, simply put, is this: We have an array of grades representing the performance of students. Each student must receive at least one candy. A student with a higher rating than their nearby must receive more candy than that adjacent. The objective is to find the least total number of candies needed to satisfy these requirements.

The naive approach – assigning candies sequentially while ensuring the relative order is maintained – is slow. It fails to exploit the inherent pattern of the problem and often leads to excessive calculations. Therefore, a more refined strategy is required, leveraging the power of dynamic computational thinking.

### A Two-Pass Solution: Conquering the Candy Conundrum

A highly effective resolution to LC135 v1 involves a two-pass approach. This stylish method elegantly manages the constraints of the problem, ensuring both effectiveness and precision.

The first pass goes through the array from start to right. In this pass, we assign candies based on the relative grades of adjacent elements. If a child's rating is greater than their preceding adjacent, they receive one more candy than their neighbor. Otherwise, they receive just one candy.

The second pass traverses the array in the contrary direction, from right to start. This pass corrects any disparities arising from the first pass. If a child's rating is greater than their right adjacent, and they haven't already received enough candies to satisfy this condition, their candy count is updated accordingly.

This two-pass algorithm guarantees that all conditions are met while minimizing the total number of candies assigned. It's a superior example of how a seemingly complex problem can be broken down into smaller, more manageable subproblems.

**Illustrative Example:**

Let's consider the grades array: `[1, 3, 2, 4, 2]`.

- **First Pass (Left to Right):**
- Child 1: 1 candy (no left neighbor)
- Child 2: 2 candies (1 + 1, higher rating than neighbor)
- Child 3: 1 candy (lower rating than neighbor)
- Child 4: 2 candies (1 + 1, higher rating than neighbor)
- Child 5: 1 candy (lower rating than neighbor)
- **Second Pass (Right to Left):**
- Child 5: Remains 1 candy
- Child 4: Remains 2 candies
- Child 3: Remains 1 candy
- Child 2: Remains 2 candies
- Child 1: Becomes 2 candies (higher rating than neighbor)

The final candy distribution is `[2, 2, 1, 2, 1]`, with a total of 8 candies.

**Practical Applications and Extensions:**

The core idea behind LC135 v1 has uses beyond candy allocation. It can be adapted to solve problems related to resource assignment, priority sequencing, and optimization under conditions. For instance, imagine assigning tasks to workers based on their skills and experience, or allocating budgets to projects based on their expected returns. The principles learned in solving LC135 v1 can be readily employed to these scenarios.

**Conclusion:**

LC135 v1 offers a significant lesson in the art of dynamic algorithm design. The two-pass answer provides an efficient and elegant way to address the problem, highlighting the power of breaking down a difficult problem into smaller, more tractable parts. The principles and techniques explored here have wide-ranging implications in various domains, making this problem a rewarding exercise for any aspiring computer scientist.

**Frequently Asked Questions (FAQ):**

**1. Q: Is there only one correct solution to LC135 v1?**

**A:** No, while the two-pass approach is highly efficient, other algorithms can also solve the problem. However, they may not be as effective in terms of time or space usage.

**2. Q: What is the time consumption of the two-pass resolution?**

**A:** The time usage is  $O(n)$ , where  $n$  is the number of scores, due to the two linear passes through the array.

**3. Q: How does this problem relate to other dynamic algorithm design problems?**

**A:** This problem shares similarities with other dynamic algorithm design problems that involve optimal substructure and overlapping subproblems. The resolution demonstrates a greedy method within a dynamic programming framework.

**4. Q: Can this be solved using a purely greedy technique?**

**A:** While a purely greedy method might seem intuitive, it's likely to fail to find the least total number of candies in all cases, as it doesn't always guarantee satisfying all constraints simultaneously. The two-pass approach ensures a globally optimal solution.
